- 17 Mechanistic Modelling of Recurrent Epidemics V

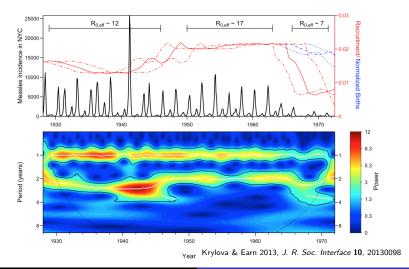

# Mechanistic Modelling of Recurrent Epidemics

### Measles in New York City

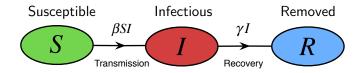

Instructor: David Earn Mathematics 4MB3/6MB3 Mathematical Biology

# Mechanistic Epidemic Modelling: Principles

- Consider the biological mechanisms involved in disease transmission and spread
- Model mechanisms and infer their effects
- Start as simple as possible!
- Rule out simple models by comparing results with observed time series of incidence or mortality
- Add complexity one step at a time, so key mechanisms can be identified
- Ideally converge on simplest possible model that can explain observed patterns

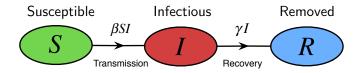

# The SIR model: Flow Chart and Parameters

$$\frac{dS}{dt} = -\beta SI$$
$$\frac{dI}{dt} = \beta SI - \gamma I$$
$$\frac{dR}{dt} = \gamma I$$

- Parameters:
  - **Transmission** rate  $\beta$
  - Recovery rate γ
     (or Removal rate)

# The SIR model: Derived Parameters

$$\frac{dS}{dt} = -\beta SI$$
$$\frac{dI}{dt} = \beta SI - \gamma I$$
$$\frac{dR}{dt} = \gamma I$$

### Derived Parameters:

- $\label{eq:basic} \blacksquare \mbox{ Initial growth rate } \beta \gamma$
- Mean infectious period  $\frac{1}{\gamma}$
- Basic Reproduction Number

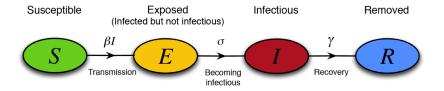

$$\mathcal{R}_0 = \frac{\beta}{\gamma}$$

### Basic SIR Model: Important Results

- Epidemic occurs if and only if  $\mathcal{R}_0 > 1$
- Exact solution for phase portrait
- Single epidemic, then disease disappears
- Exact formula for final size as a function of  $\mathcal{R}_0$
- Cannot explain diseases that persist
- Cannot explain recurrent cycles of epidemics

### What are we missing?

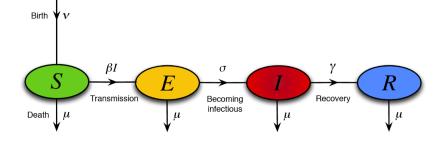

- Introduces only one new parameter  $(\sigma)$
- Mean latent period  $(1/\sigma)$  can often be estimated
- But... effect of inclusion of exposed class usually small

### What are we still missing?

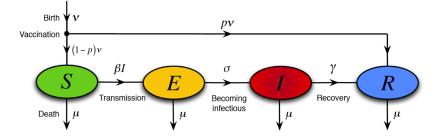

### SEIR Model with vital dynamics: flow chart

New Parameters:

- Birth rate (ν for natality)
- Death rate (µ for mortality)
- Mean latent period  $(1/\sigma)$

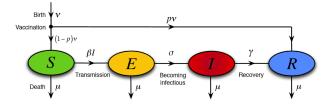

# SEIR with vital dynamics and vaccination: flow chart

New Parameters:

- Birth rate (v for natality)
- Death rate (µ for mortality)
- Mean latent period  $(1/\sigma)$
- Proportion vaccinated (p)

# SEIR with vital dynamics and vaccination: Equations

$$\frac{dS}{dt} = \nu(1-p) - \beta SI - \mu S$$

$$\frac{dE}{dt} = \beta SI - \sigma E - \mu E$$

$$\frac{dI}{dt} = \sigma E - \gamma I - \mu I$$

$$\frac{dR}{dt} = \nu p + \gamma I - \mu R$$

- Birth rate (v for natality)
- Death rate (µ for mortality)
- Proportion vaccinated (p)
- Transmission rate (β)
- Mean latent period  $(1/\sigma)$
- Mean infectious period  $(1/\gamma)$

# Mathematics and Statistics

$$\int_{M} d\omega = \int_{\partial M} \omega$$

# Mathematics 4MB3/6MB3 Mathematical Biology

Instructor: David Earn

### Lecture 13 Mechanistic Modelling of Recurrent Epidemics Monday 5 February 2018

### Announcements

# Assignment 2: Due TODAY! Do the Group contribution survey TODAY.

Assignment 3 is posted.
 Due Wednesday 28 February 2018, 11:30am.

### Midterm test:

- Date: Thursday 8 March 2018
- *Time:* 7:00pm to 9:00pm
- Location: BSB-B154

#### 19/85

### SEIR with vital dynamics and vaccination: Analysis

■ *R*<sub>0</sub> ?

- Biological derivation: (assuming  $\nu = \mu$  and p = 0)  $\mathcal{R}_0 = \beta \times \frac{\sigma}{\sigma + \mu} \times \frac{1}{\gamma + \mu} \simeq \frac{\beta}{\gamma} \quad \because \frac{1}{\mu} \gg \max\left(\frac{1}{\sigma}, \frac{1}{\gamma}\right)$
- Mathematical derivation:
   \$\mathcal{R}\_0 = 1\$ is stability boundary
- Final size ? Not well defined (because of continuous source of new susceptibles).
- Equilibria ?
  - Disease Free Equilibrium (DFE)
  - Endemic Equilibrium (EE)
  - That's all folks.
- Periodic solutions ? No.
- What else ? Chaos?

### SEIR with vital dynamics and vaccination: Results

- $\exists$  Endemic Equilibrium  $\iff \mathcal{R}_0(1-p) > 1$ 
  - EE is GAS in this case.
  - DFE is GAS otherwise.
- Eradication  $\iff p > 1 \frac{1}{\mathcal{R}_0}$  (herd immunity)
  - Smallpox:  $\mathcal{R}_0 \sim 4 \implies p_{\mathrm{crit}} \sim 75\%$
  - Measles:  $\mathcal{R}_0 \sim 20 \implies p_{\mathrm{crit}} \sim 95\%$
- Explains persistence of diseases (via births)
- No periodic solutions  $\stackrel{?}{\Longrightarrow}$  no recurrent epidemics
- $\blacksquare$  GAS equilibrium  $\implies$  no periodic solutions and no chaos
- Equilibrium approached by *damped oscillations*
  - $\implies$  recurrent epidemics
- But observed epidemic patterns show undamped oscillations...

# What are we **STILL** missing?

# Demographic Stochasticity

- Differential equations describe the expected behaviour in the limit that the population size goes to infinity
- How do dynamics differ in finite populations?
- Re-cast the SEIR model as a stochastic process (Continuous time Markov process)
- Proving anything about stochastic epidemic models is difficult, but we can easily simulate them and learn a lot
- Standard algorithm for creating realizations of a stochastic epidemic model attributed to Daniel T. Gillespie

Gillespie 1976, J. Comp. Phys. 22, 403-434

- Rather than rates of change of compartment sizes consider event rates for transitions between disease states
- Finite number of individuals
- Assume event rates depend only on current state of population

### Gillespie Algorithm

- Let a<sub>1</sub>, a<sub>2</sub>, ..., be the rates at which the various processes occur, e.g.,
  - $a_1 = \text{birth rate},$
  - $a_2$  = rate of going from susceptible to exposed,
  - a<sub>3</sub> = the rate of going from infectious to removed (recovering),
    etc.
- Let a<sub>0</sub> be the overall event rate, *i.e.*, a<sub>0</sub> = ∑<sub>i</sub> a<sub>i</sub> (so average time between events = 1/a<sub>0</sub>).
- Assume time spent in any state is exponentially distributed (transitions between states are "Poisson processes")
- ... Probability next event occurs in (t, t + dt) is  $a_0 e^{-a_0 t} dt$
- Let  $u = 1 e^{-a_0 t}$ . Then  $u \in [0, 1]$  and  $du = a_0 e^{-a_0 t} dt$  $\implies u$  is uniformly distributed in [0, 1].
- ... Get time t to next event by sampling u from uniform distribution in [0, 1] and setting  $t = \frac{1}{a_0} \ln \frac{1}{1-u}$ .

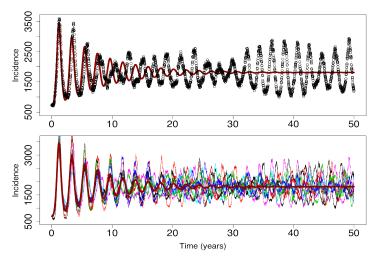

- We now know the time t of the next event, but we must still determine what type of event occurs at time t.
- Probability of event of type *i* is  $\frac{a_i}{2}$
- ... Can easily determine type of event by sampling a point from a uniform distribution on [0, *a*<sub>0</sub>]:
  - Event is type *i* if the uniform deviate lies in the *i*th interval in the following list:

 $[0, a_1), [a_1, a_1 + a_2), \ldots, [a_1 + \cdots + a_{i-1}, a_1 + \cdots + a_i), \ldots$ 

How do realizations of this process differ from the solution of the deterministic (differential equation) model?

### Gillespie Simulations: Results for Measles Parameters

 $\mathcal{R}_0=$  17,  $\mathcal{T}_{\mathrm{lat}}=$  8 days,  $\mathcal{T}_{\mathrm{inf}}=$  5 days,  $u=\mu=$  0.02/year,  $\mathit{N}=$  5,000,000

Earn 2009, IAS/Park City Mathematics Series 14, 151-186

# Effects of Demographic Stochasticity

- Sustains transient behaviour (oscillations do not damp out) (Bartlett 1950's)
- Explains undamped oscillations at a single period
- But, unable to explain changes in interepidemic period, or irregularity

# What are we **STILL** missing?

Mathematics and Statistics

$$\int_{M} d\omega = \int_{\partial M} \omega$$

# Mathematics 4MB3/6MB3 Mathematical Biology

Instructor: David Earn

### Lecture 14 Mechanistic Modelling of Recurrent Epidemics II Wednesday 7 February 2018

### Announcements

Assignment 3 is posted.
 Due Wednesday 28 February 2018, 11:30am.

### Midterm test:

- Date: Thursday 8 March 2018
- *Time:* 7:00pm to 9:00pm
- Location: BSB-B154

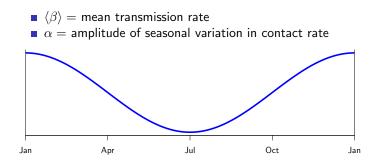

### Contact rates are higher during school terms!

### Sinusoidal SEIR Model

- Transmission rate β is not constant: high during school terms, low in summer
- For simplicity, model as a sine wave:

$$\beta(t) = \langle \beta \rangle \left( 1 + \alpha \cos 2\pi t \right)$$

- We now have a forced nonlinear system
- Forcing frequency can resonate with the natural timescales of the disease (*e.g.*, damping period)
- Very rich dynamical system... (analogy: forced pendulum)

### Sinusoidal SEIR Model: Numerical Results

- Stable cycles of various lengths (annual, biennial, 3-year, ...)
- Multiple co-existing stable cycles
- Chaotic dynamics
- Lots of work on this model in 1980s and 1990s
  - Smith HL, 1983, J. Math. Biol. 17, 163-177
  - Schwartz IB, Smith HL, 1983, J. Math. Biol. 18, 233-253
  - Aron JL, Schwartz IB, 1984, J. theor. Biol. 110, 665-679
    - Olsen LF, Schaffer WM, 1990, Science 249, 499-504

. . .

### Sinusoidal SEIR Model: Rigorous Results

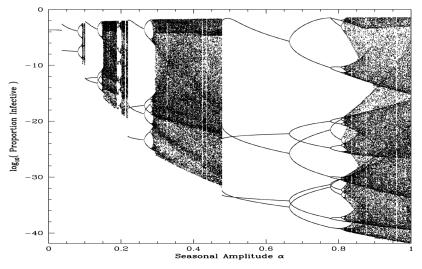

There exist parameter values such that infinitely many stable cycles co-exist

Schwartz IB, Smith HL, 1983, J. Math. Biol. 18, 233-253

There exist chaotic repellors (in a modified SEIR model)

Glendinning P, Perry LP, 1997, J. Math. Biol. 35, 359-373

### Measles Bifurcation Diagram (Sinusoidal SEIR model)

Earn (2009) IAS/Park City Mathematics Series 14, 151-186

### Does Sinusoidal SEIR Model Explain Measles Dynamics?

SEIR model with sinusoidal forcing:

- Produces recurrent undamped epidemics of all frequencies observed in measles time series.
- Produces chaos, which can explain irregular behaviour and transitions from one type of cycle to another
  - If correct, this implies these transitions are *unpredictable*.
- BUT... the model also predicts rapid extinction of the virus (not persistence).

# What are we **STILL** missing?

# Is Age Structure Important?

- Real system is not homogeneously mixed
- Contact structure is age-dependent
- Schenzle (1984) argued for creating a Realistically Age-Structured (RAS) SEIR model
  - 21 age classes (0–1, 1–2, ..., 19–20, > 20)
  - SEIR compartments for each age class
  - Different contact rates between all these age classes

$$\beta(t) \longrightarrow \begin{pmatrix} \beta_{1,1}(t) & \beta_{1,2}(t) & \cdots & \beta_{1,21}(t) \\ \beta_{2,1}(t) & \beta_{2,2}(t) & \cdots & \beta_{2,21}(t) \\ \vdots & \vdots & \ddots & \vdots \\ \beta_{21,1}(t) & \beta_{21,2}(t) & \cdots & \beta_{21,21}(t) \end{pmatrix}$$

Schenzle D (1984) IMA Journal of Mathematics Applied in Medicine and Biology 1, 169–191

Lots of work on RAS models since Schenzle (1984)

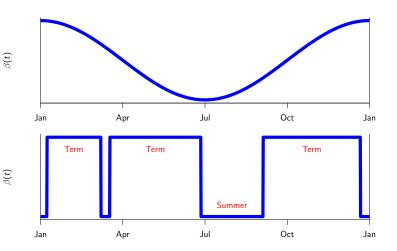

# RAS SEIR model: Results for Measles

- Persistent biennial cycle
- Matches biennial cycle in data extremely well
- And we need only 84 ODEs and fewer than 500 new parameters!
- Can get an even better fit by adding spatial structure with 6000 ODEs and only 1500 new parameters!
- Woohoo! Time to celebrate.
- hmmm...maybe not...
- In fact, age structure is a RED HERRING!
- Critical ingredient of RAS model is...

## Contact rates are higher during school terms!

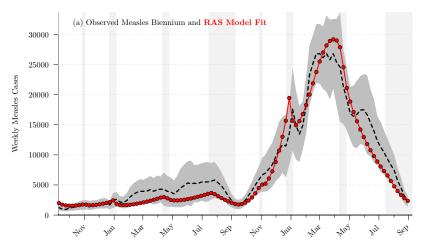

#### Sinusoidal forcing vs Term-time forcing

#### Lecture 15 Mechanistic Modelling of Recurrent Epidemics III Friday 9 February 2018

#### Announcements

- Thanks for re-doing the survey for Assignment 2.
- Assignment 3 is posted.

Due Wednesday 28 February 2018, 11:30am.

#### Midterm test:

- Date: Thursday 8 March 2018
- *Time:* 7:00pm to 9:00pm
- Location: BSB-B154

#### Term-time SEIR model: Results for Measles

- Fits measles time-series just as well as full RAS model (RAS fit versus Term-time SEIR fit)
  - No need for hundreds of new parameters!!
- Conclude: explicit age structure is unnecessary
  - To understand aggregate measles time series
    - In particular, unnecessary for disease persistence

Earn, Rohani, Bolker, Grenfell (2000) Science 287, 667-670

- But age-structured models do have their place
  - To investigate age-structured data
  - To explore effects of age-structured control strategies

# Term-time SEIR model: Does it explain measles dynamics?

- Can we explain the many different patterns of measles epidemics with the same model?
  - The sinusoidal SEIR model could do that via chaos.
  - Term-time SEIR model predicts a strictly biennial cycle of measles epidemics, at all times and places.
  - Is superb agreement with post-war measles dynamics in London and New York *coincidental???*

# What **ELSE** might we be missing?

#### 49/85

#### Let's review what we've learned so far

#### What helps us explain temporal measles dynamics?

- Some key, biologically meaningful parameters
  - Basic reproductive ratio  $(\mathcal{R}_0)$ 
    - Transmissibility.
    - Can an epidemic occur? If so, how big?
  - Amplitude of seasonal forcing  $(\alpha)$ 
    - Magnitude of seasonal variation in contact rate.
    - Stable, sustained oscillations or chaos.
- Some parameters are *less important* than previously thought
  - Age-structured mixing rates
    - Whew! Hard to estimate all those parameters anyway...
  - Spatially-structured mixing rates
    - Whew! Hard to estimate all those parameters anyway...

#### 50/85

#### Let's review how our analysis has proceeded

- Considered a sequence of mechanistic mathematical models of measles transmission dynamics
- Ruled out:
  - Simple SIR and SEIR models, even with vital dynamics and vaccination (oscillations damp out)
  - Stochastic SEIR model (undamped oscillations at only one frequency)
  - Sinusoidally forced SEIR model (pathogen goes extinct)
- Best model so far:
  - Term-time forced SEIR model
    - Excellent description of post-war biennial measles dynamics in New York and London
    - BUT: appears unable to explain changes in pattern of epidemics over long time scales
    - Humph.

#### Hmmm...

- What should we try next?
- Do we need more model structure?
- We changed  $\beta \rightarrow \beta(t)$ . Do other parameters vary significantly with time?
  - Birth rate?
  - Death rate?
  - Vaccination rate?
  - Other parameters?

#### 52/85

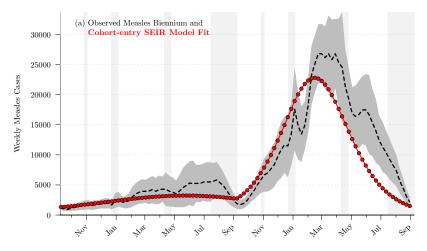

## Cohorts

- The RAS model fit was based on simplifying assumptions about the transmission matrix  $(\beta_{ij}(t))$  in order to reduce the number of parameters.
- Perhaps we can do better—still without age-structure—but including the cohort effect:
  - In the RAS model, everyone moves up one cohort at the start of each school year.
  - Consequently, it is <u>as if</u> most births occur on the first day of school each year ("impulsive births").
  - What is the dynamical influence of the cohort effect?

He & Earn (2016) J. R. Soc. Interface 13, 20160156

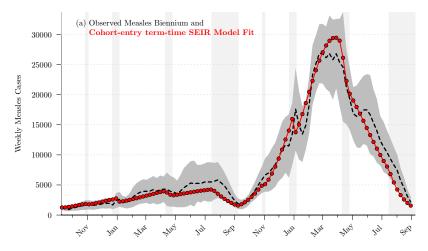

Compare fits of measles biennium in England and Wales with:
 (i) RAS, (ii) term-time, (iii) cohort, (iv) term-time and cohort.

#### Cohort SEIR model fit to measles in England and Wales

He & Earn (2016) J. R. Soc. Interface 13, 20160156

#### Term-time cohort SEIR model fit to measles in E&W

He & Earn (2016) J. R. Soc. Interface 13, 20160156

#### 55/85

#### Cohort effect: summary

- Cohort effect alone (without transmission rate forcing) is sufficient to generate all the types of dynamics observed in models with seasonal forcing of the transmission rate (different dynamics obtained from different proportions of "births" occurring at start of school year).
- The source of seasonal forcing affects the detailed shape of the time series, but not the potential for complex dynamics.
- The best fit to the England and Wales measles biennium is obtained with term-time forcing together with the cohort effect.
  - Nevertheless, we will ignore the cohort effect because it complicates the model without helping us get to the bottom of the *changes* in dynamical structure over time.
- This does not address the issue of dynamical structure changing over time...

### Effects of slow changes in birth rate

Consider SIR model with *B* births per unit time  $(B \neq \mu N)$ :

Suppose birth rate changes from B to  $\tilde{B}$ :

$$\frac{dS}{dt} = B - \beta SI - \mu S \qquad \qquad \frac{dS}{dt} = \tilde{B} - \beta SI - \mu S$$
$$\frac{dI}{dt} = \beta SI - \gamma I - \mu I \qquad \qquad \frac{dI}{dt} = \beta SI - \gamma I - \mu I$$
$$\frac{dR}{dt} = \gamma I - \mu R \qquad \qquad \frac{dR}{dt} = \gamma I - \mu R$$

• How are dynamics affected by the change from B to  $\tilde{B}$  ?

## Effects of slow changes in birth rate

Consider change of variables in second system with birth rate  $\tilde{B}$ :

$$S o \tilde{S} rac{ ilde{B}}{B}, \qquad I o \tilde{I} rac{ ilde{B}}{B}, \qquad R o ilde{R} rac{ ilde{B}}{B}$$

Birth rate B:

Birth rate  $\tilde{B}$ :

 $\frac{dS}{dt} = B - \beta SI - \mu S \qquad \qquad \frac{d\tilde{S}}{dt} = B - \frac{\beta \tilde{B}}{B} \tilde{S} \tilde{I} - \mu \tilde{S}$  $\frac{dI}{dt} = \beta SI - \gamma I - \mu I \qquad \qquad \frac{d\tilde{I}}{dt} = \frac{\beta \tilde{B}}{B} \tilde{S} \tilde{I} - \gamma \tilde{I} - \mu \tilde{I}$  $\frac{dR}{dt} = \gamma I - \mu R \qquad \qquad \frac{d\tilde{R}}{dt} = \gamma \tilde{I} - \mu \tilde{R}$ 

System with birth rate  $\tilde{B}$  is identical (up to scaling) to system with birth rate B with transmission rate  $\beta \tilde{B}/B$ .

# Key Insight

- Suppose R<sub>0</sub> is estimated during a period when the birth rate is B
- If the birth rate changes to B then the dynamical effect is identical to changing R<sub>0</sub> instead:

$$\mathcal{R}_0 \longrightarrow \mathcal{R}_0 \frac{\tilde{B}}{B}$$

 Similarly, if the birth rate is B and a vaccination programme is initiated (vaccinating a proportion p of newborns) then the dynamical effect is identical to

$$\mathcal{R}_0 \longrightarrow \mathcal{R}_0(1-p)$$

More generally, any change in susceptible recruitment rate is equivalent dynamically to a change in R<sub>0</sub>.

## Predicting Epidemic Transitions

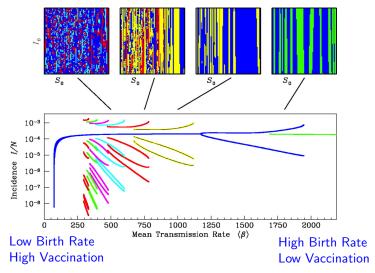

#### Changes in

- Birth rate  $(\nu)$
- Vaccination proportion (p)
- Transmission rate ( $\beta$  or  $\mathcal{R}_0$ )

all map onto the same parameter axis.

- ... We can summarize possible dynamical changes induced by demographic/behavioural changes with a one-parameter bifurcation diagram.
- . We can predict epidemic transitions by mapping observed changes in  $\nu$ , p or  $\mathcal{R}_0$  onto this diagram.
- So let's try to do that for measles!

#### Measles Bifurcation Diagram (wrt $\langle \beta \rangle \simeq \gamma \mathcal{R}_0$ )

Earn, Rohani, Bolker, Grenfell (2000) Science 287, 667-670

- The project descriptions ask you questions and suggest directions for investigation, but you must construct the final document as a coherent single manuscript, not answers to a bunch of questions.

#### Last time...

- Discussed R<sub>0</sub> bifurcation diagram that predicts effects of slow changes in birth rate, vaccination proportion or R<sub>0</sub> (in general effects of changes in *susceptible recruitment rate*).
- Successfully explains measles time series in London and Liverpool (UK) and New York City and Baltimore (USA).
- Sadly <u>fails</u> to explain any other childhood disease time series!
- Yet changes in susceptible recruitment do seem to be associated with transitions in patterns of epidemics of other childhood diseases.

# What are we **STILL** missing?

# Demographic Stochasticity Comes to the Rescue (Again!)

- Sustains transient behaviour
- Linear perturbation theory applied to the attractors of the model explains other spectral peaks in data

Whew!

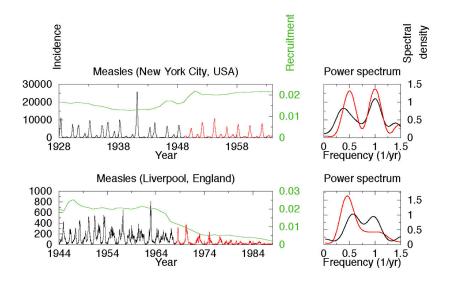

#### Get More Ambitious!

- Aim to predict all spectral peaks in the data
- Predict Resonant peaks from asymptotic analysis
- Predict Non-resonant peaks from perturbation analysis
- Predictions are accurate for rubella and whooping cough

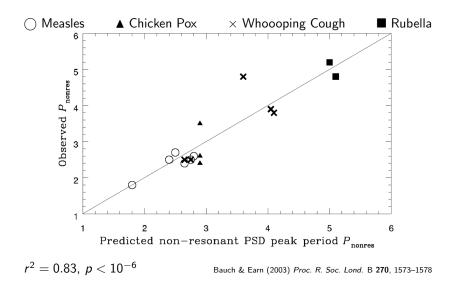

Bauch & Earn (2003) Proc. R. Soc. Lond. B 270, 1573-1578

Can we explain more details of measles dynamics?

### Another Look at Measles

# Predicted vs Observed Non-Resonant Spectral Peaks

# Summary so far

- Perfect prediction of resonant peaks
- Excellent prediction of non-resonant peaks ( $p < 10^{-6}$ )

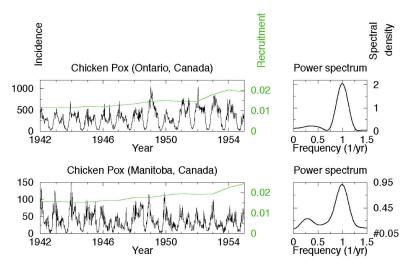

#### Yippee!

- Get even more ambitious...
- Can we predict magnitudes of spectral peaks?

#### 80/85

### Can we predict magnitudes of spectral peaks?

Example: Chicken Pox in Ontario vs Manitoba

# Demographic Stochasticity

#### Sustains transient behaviour

Bartlett 1950s

#### ■ Greater stochasticity in smaller populations ⇒ larger non-resonant peaks

#### Confirmed with stochastic simulations

Bauch & Earn (2003) Proc. R. Soc. Lond. B 270, 1573-1578

## Summary: Modelling recurrent epidemics

- We now understand recurrent epidemic patterns of many infectious diseases (*e.g.*, measles, chicken pox, whooping cough, rubella, ...)
- Perfect prediction of resonant spectral peaks
- Excellent prediction of non-resonant spectral peaks
- Population size is key determinant of relative magnitude of resonant vs non-resonant peaks (can only get at this with simulations at present)

## Summary: Key Parameters

Basic reproductive ratio:  $\mathcal{R}_0$ 

- Threshold for an epidemic to occur
- Amplitude of seasonal forcing:  $\alpha$ 
  - Sustained oscillations of different frequencies
- Effective reproductive ratio:  $\mathcal{R}_0(1-p)\nu'/\nu$ 
  - Transitions in epidemic frequency/pattern
- Population size: N
  - Relative magnitude of spectral peaks

### Can We Estimate the Key Parameters?

- Basic reproductive ratio:  $\mathcal{R}_0$ 
  - Yes, e.g., via mean age at infection
- Amplitude of seasonal forcing:  $\alpha$ 
  - Difficult: must use the disease time series itself
  - If possible, estimate from time series for several different diseases in same place and same time period
- Effective reproductive ratio:  $\mathcal{R}_0(1-p)\nu'/\nu$ 
  - Yes, vaccination and birth rates are documented
- Population size: N
  - Yes, well known.

# Advice to Take Home

- Start simple!!!
  - Don't add more structure and more parameters unless you're sure that the simpler model with fewer parameters is not adequate to explain the phenomena of interest.
- Increase complexity in steps
  - Rule out simpler models first
  - Try to add one parameter at a time, and if possible then do this independently for different parameters before trying to analyze a model with several new parameters.
- Beware of parameters that cannot be estimated
  - Results are only as reliable as your parameter guesses
  - Useful only to examine potential influences of mechanisms
